

ADR-001 : Choix de la solution d'Intégration et de Déploiement Continu (CI/CD)

Contexte

As part of the platform's development, we need to automate test execution and deployment. The goal is to streamline future production deployments and efficiently manage our containerization workflows (Docker Compose). We need a reliable tool to run our pipelines every time the code is changed.

Options considérées

- GitHub Actions : Native integration with the code repository, a rich ecosystem with numerous preconfigured actions, and simplified management of variables and secrets.
- GitLab CI : A very powerful and comprehensive solution, but one that would require migrating the codebase to GitLab or setting up complex mirrors.
- Jenkins : An extremely robust and customizable tool, but one that requires the installation, hosting, and maintenance of a dedicated server solely for CI/CD.

Décision

Use GitHub Actions.

Justification : Since the tool is directly integrated where the code is hosted, setup is immediate and seamless. It integrates perfectly with our containerization needs and our various cloud deployment targets. Furthermore, it saves us from having to allocate time and resources to maintaining a dedicated CI infrastructure, as would be the case with Jenkins.

Conséquences

- Positive : Very quick setup, excellent documentation, and CI infrastructure maintenance fully delegated to GitHub.
- Positive : Centralizing the source code and pipelines in one place, which makes onboarding easier.
- Négative : Heavy reliance on the GitHub ecosystem.
- Négative : Limits on free minutes for running runners on private repositories (although these are generally sufficient for the current phase of the project).
