

ADR-003 : Maintaining Jest as the testing framework

Contexte

To ensure the reliability of our application, we need to write and execute unit and integration tests. The Jest testing framework was already initialized in the project's existing codebase.

Options considérées

- Keep Jest : A tool already in place, comprehensive (includes test runner, assertions, and mocks), and a standard in the ecosystem.
- Migrate to Vitest: A newer and faster framework, highly performant, but requiring migration and reconfiguration efforts for the existing setup.
- Migrate to Mocha/Chai/Sinon: An older stack, requiring the combination of multiple libraries to achieve the same functionalities.

Décision

Keep and Use Jest.

Justification : The tool was already present in the project. Given that it perfectly meets our current needs for testing the application and integrates naturally with our technical stack, there is no added value in investing time to migrate to another framework. Pragmatism prevails here: we keep what works so we can focus on development

Conséquences

- Positive : No cost or time spent on migration or initial configuration.
- Positive : A well-documented, all-in-one tool
- Négative : Potentially less optimal execution speed compared to newer tools (like Vitest) if the test suite becomes very large.
